(view original):. The Windows 10 Anniversary Update may have opened some doors to improve your browsing experience. In this guide, we show you the best options for browsing the Web with Mozilla Firefox and Google Chrome. Key Layers The term “key layers” refers to the items that are used to identify which of the devices or users are accessing a given web page. A particular website’s key layers might include the following components: A unique URL. An HTTP referrer (the link that led the user to the site). A set of cookies. The IP address that the user’s device used to access the site. The user agent (the software that the user’s browser is using to access the site). A website’s key layers will differ from visitor to visitor. For example, one visitor might have the user agent set to the latest Firefox release, while a different visitor might be using Internet Explorer, with the same referrer. The goal of a security measure is to make it harder for someone who has compromised a user’s browser to access

a website or service that they should not be allowed to access. A security measure that blocks all HTTP referrers will make it much harder for an attacker to find a vulnerable website. These are all things that a website might include in its key layers. Each of these items is known as a “key” in the security industry, and security engineers have developed the best ways to block access to websites that are using the data associated with each key. The purpose of this article is to explain the current rules for key layers, and why they are important. Why we use referrers When you type in a URL, a web browser performs two main tasks: It loads the requested web page. It makes sure that the web page is being loaded from the correct URL. One of the most common ways that a website owner’s web server communicates the request for a web page to a visitor’s web browser is via an HTTP referrer. For example, if you’re currently on YouTube and you click on a link that goes to a page that has an embedded video, the link that you click on might have the following HTTP referrer information: 82157476af
